Introduction to the Laplace Transform

One of the basic problem solving techniques in mathematics is to

- transform a difficult problem into an easier one,
- solve the easier problem, and
- then use its solution to obtain a solution of the original problem.

$$3y'' + 2y' + 6y = 0$$

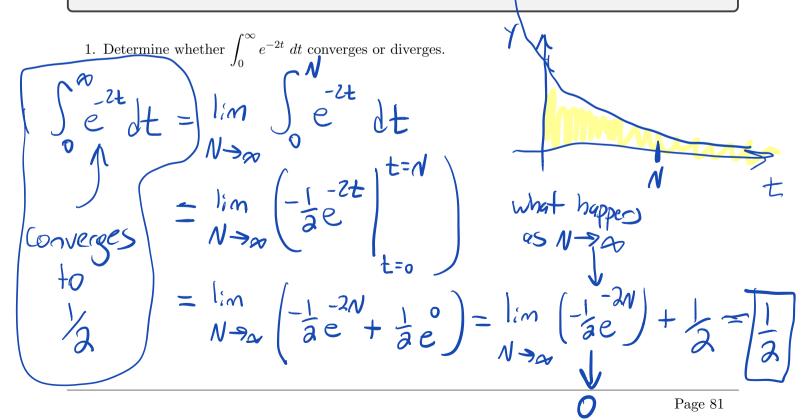

For example, the reverse product rule (method of integrating factor) is used to transform a linear first order differential equation into an easier problem we can solve. In this chapter we study the method of **Laplace transforms**, which is one example of this technique. Like the method of integrating factors, Laplace transforms are **integral operators**. Solving by the method of Laplace transforms:

- Can be used to solve higher order linear differential equations.
- Can be applied for more complicated forcing functions.
- Requires initial conditions.

The **improper integral** of g over $[a, \infty)$ is defined as

$$\int_{a}^{\infty} g(t) \ dt = \lim_{N \to \infty} \int_{a}^{N} g(t) \ dt.$$

- \bullet We say the improper integral ${\bf converges}$ if the limit exists.
- Otherwise we say the improper integral diverges.

Definition of the Laplace Transform

Let f(t) be a function on $[0,\infty)$. The **Laplace transform** of f is the function F defined by

$$\mathcal{L}\{f\} = F(s) = \int_0^\infty e^{-st} f(t) dt.$$

- ullet The domain of F(s) is all values of s for which the integral converges.
- The functions f and F form a **transform pair**.
- 2. Find and state the domain of the Laplace transform $F(s) = \mathcal{L}\{f(t)\}$.
